Assignment 2

CS834-F16: Introduction to Information Retrieval Fall 2016 Erika Siregar

Plot rank-frequency curves (using a log-log graph) for words and bigrams in the Wikipedia collection available through the book website (http://www.searchengines-book.com). Plot a curve for the combination of the two. What are the best values for the parameter c for each curve?

Answer

For this question, I use the 'Wiki small' test collections which can be downloaded from http://www.searchengines-book.com. Plotting the rank-frequency values can be done using these following steps:

- 1. Traverse the directory containing the test collections and list all the HTML files in that directory.
- 2. Get the text content from each HTML files using a python library 'html2text' [1]. I think using this library is simpler than using 'Beautiful Soup' [2]. It also gives us a cleaner 'html-stripped' result.
- 3. Tokenize the text using function 'text.split()' and 'word.isalpha()'. Each token is equal to one word.
- 4. Create the bigrams using function nltk.bigrams() provided by python library 'nltk' [3].
- 5. For both tokens and bigrams, do:
 - (a) Count their frequencies (the number of times they appear in the whole collections).
 - (b) Rank the tokens and the bigrams. The token or bigram that have the highest frequency will have rank = 1. The second highest frequency token or bigram will have rank = 2, and so on.
 - (c) Compute their probability and the 'c' value.
- 6. Write the output to a csv file.

The complete code for the steps above can be seen in listing 1.

```
2 #!/usr/bin/python
3 import io
  import os
6 import html2text
7 import unicodecsv as csv
8 import nltk
10 \text{ html} \text{ files} = []
11 # traverse the directory to list all the html files in the directory
12 for root, dirs, files in os.walk(os.path.abspath('./articles')):
       for file in files:
13
           if file.endswith('.html'):
14
               filepath = os.path.join(root, file)
15
               html files.append(filepath)
16
18 #html files = html files [:10]
```

```
tokens = []
  # process each html file
  for idx, file in enumerate(html_files):
       print('{} of {}. Processing {}'.format(idx+1, len(html_files), file))
23
       print ('=' * 30)
24
25
      # get text only from each file -> remove all tags
26
      h = html2text.HTML2Text()
27
      h.ignore\_links = True
28
       text = h.handle(u' '.join([line.strip() for line in io.open(file, "r", encoding="
29
      utf-8").readlines()]))
30
31
      # get all words from text by splitting by whitespace
       for word in text.split():
32

Table 2: Most frequent 20 bigrams from Wikipedia Collection (Wiki small)

We just finished doing the first part of our task, which are creating tokens and bigrams. Next step is plotting the rank-frequency values of the tokens and bigrams into a log-log graph. There are 3 graph that we will create using R [4]:

- 1. A log-log rank-frequency plot for the words.
- 2. A log-log rank-frequency plot for the bigrams.
- 3. The combination of log-log rank-frequency plot for words and bigrams.

Figures 1, 2 show the log-log rank-frequency plot for the words, bigrams, and the combination of words and bigrams, respectively. Instead of frequency, I use probability for the y-axis.

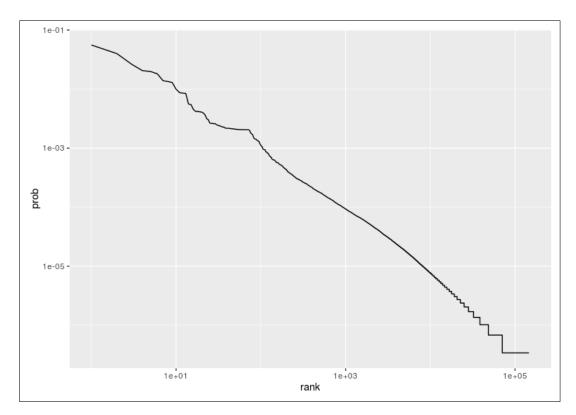

Figure 1: Log-log rank-frequency for words in Wikipedia Collection (Wiki small)

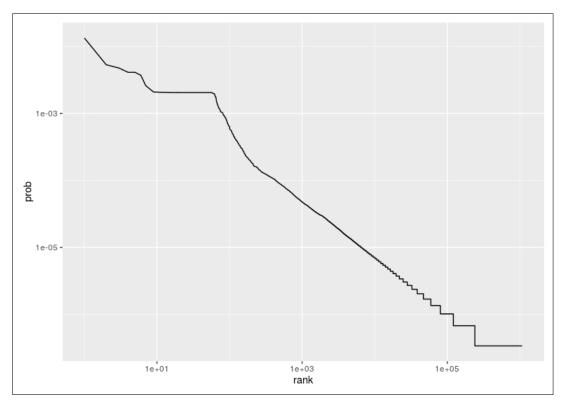

Figure 2: Log-log rank-frequency for bigrams in Wikipedia Collection (Wiki small)

Plot vocabulary growth for the Wikipedia collection and estimate the parameters for Heaps' law. Should the order in which the documents are processed make any difference?

Answer:

The idea to solve this problem is simply calculated the number of words in every document and store it as 'corpus'. Beside that, we also calculate the number of unique words in every document and store it as 'vocabulary'. Then, we can create the plot of vocabulary growth using R. Figure 3 show the plot for vocabulary growth for the Wikipedia collection.

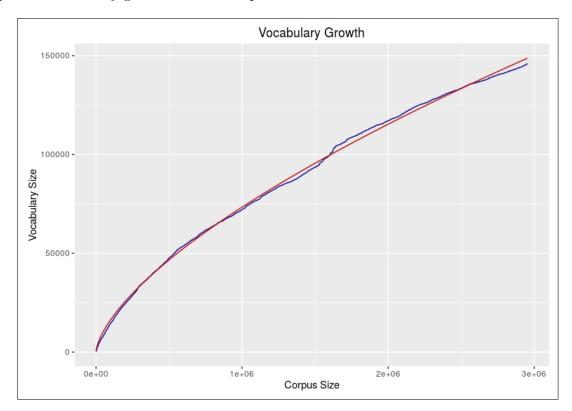

Figure 3: Vocabulary growth for the Wikipedia Collection (Wiki small)

To find out whether or not the order of document processing affect the vocabulary growth, I modify the code so that the documents are being processed in reversed order. Figure 4 shows the plot for vocabulary growth for the Wikipedia collection in reversed order.

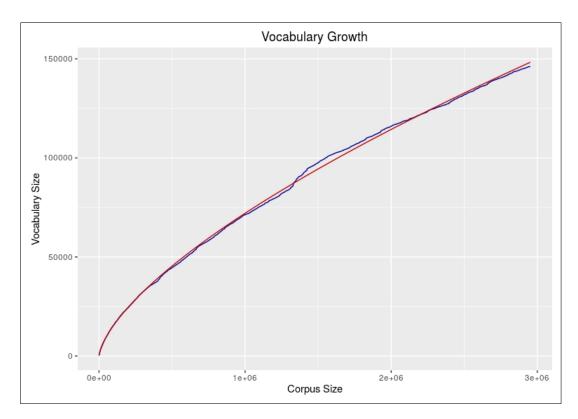

Figure 4: Vocabulary growth for the Wikipedia Collection (Wiki small)

The complete code for calculating the vocabulary growth can be seen in listing 2

```
1 #!/usr/bin/python
 2 import io

Listing 3: Code for plotting vocabulary growth and calculating the Heap's parameter

Process five Wikipedia documents using the Porter stemmer and the Krovetz stemmer. Compare the number of stems produced and find 10 examples of differences in the stemming that could have an impact on ranking.

Answer

Stemming using Porter stemmer is quite easy to do since this stemmer is provided by nltk [5]. Fortunately, there is also a python library for stemming with Krovetz algorithm [6]. So, our task now is to create a script that utilizes these 2 libraries. The logic is simple: get the text content of the documents and use Porter and Krovetz for stemming.

To do the stemming, I randomly choose 5 documents from the Wikipedia collections. These 5 documents are:

- $1.~ABC_Wasp_3b25.html$
- 2. ABC In Concert 6d5f.html
- 3. Abdus_Salam_(disambiguation)_0602.html
- 4. Abd-Allah_ibn_Amr_f58f.html
- 5. Abdul_Haq_Vidyarthi_582b.html

Figure 5 shows the comparison of stemming result between Porter and Krovetz. I circle some of the words that I consider will affect the ranking. The complete stemming result for all 5 documents is uploaded on github under a file named '4 6-result rev3.txt'.

Stemmer result of articles/a/b/c/ABC Wasp 3b25.html

Figure 5: Stemming comparison (Porter vs Krovetz)

Table 5 show 10 differences in the stemming between Porter and Krovetz that could have impact on ranking. From this table we can see that Porter arbitrally dissect the words. For example, Porter stem the word 'united' into 'unit', which have different meaning. Moreover, when this word is combined with the word next to it, they form different term. The term 'united states' is clearly different with 'unit state'. Therefore, we can see that it will definetely impact the ranking. The comparison of the number of stems produces by both Porter and Krovetz can be seen on table 4. From table 4 we can see that Krovetz produced more stems compare to that of Porter. This is because Porter is more naive in 'stemming' the word. So, there could be two words that are grouped together into the same stem while, in fact, they do not belong in the same stem.

Listing 4: Source code for stemming document using Porter Stemmer and Krovetz Stemmer

Find the 10 Wikipedia documents with the most inlinks. Show the collection of anchor text for those pages.

Answer

Here is the algorithm to find the document with the most inlinks:

- 1. Use Beautiful Soup [2] to extract all links from the Wikipedia documents.
- 2. Store the links in a key-value format, where key = document and value = link.
- 3. Group and count the links by the destination (the one that is written in 'href'). This will be the number of inlinks for each destination.
- 4. Sort the data by the number of inlinks in a descending order.

Table 6 shows 10 Wikipedia documents with the most inlinks and their anchor text.

No	Link	Inlinks	Anchor Text
1	Brazil.html	83	Brazil, BRA, Brazilian
2	August_26.html	25	08-26, 26, August 26, 26 August
3	Manga.html	14	manga, Manga
4	Magazine.html	13	magazine, magazines, Magazine
5	Mollusca.html	12	Mollusca
6	Victoria_of_the_United_Kingdom_5e8e.html	8	Queen Victoria, Queen, Victoria of the United Kingdom, Victoria
7	Screenwriter.html	7	Writer(s), screenwriter, Screenwriter
8	Kidney.html	6	kidneys, Renal, kidney
9	Tottenham_Hotspur_F.C6bd2.html	5	Tottenham Hotspur, Tottenham
10	Tuscany.html	4	Tuscany

```

Listing 5: Source code for finding 10 Wikipedia documents with the most inlinks

Write a program that can build a simple inverted index of a set of text documents. Each inverted list will contain the file names of the documents that contain that word. Suppose the file A contains the text "the quick brown fox", and file B contains "the slow blue fox". The output of your program would be:

```
% ./your-program A B
blue B
brown A
fox A B
quick A
slow B
the A B
```

Answer

To create an inverted index, we need to 'swap' the role of words vs documents. There are many nice examples that we can find on the internet about how to create inverted index. One that I find easier to understand is the one provided by RosettaCode.org [7]. The algorithm is quite simple:

- 1. List all words in each document. We will get a key-value pair, where document is the key and words are the value.
- 2. 'Swap' the role of words and documents. Now, word is the key and document is the value.
- 3. Write the output to a csv file.

The source code for the inverted index can be seen in listing 6. This code run using terminal input (figure 6).

```
erikaris@inspiron-7368:/media/erikaris/DATA/ODU/Semester 3/intro_to_info_retrieval/aserikaris@inspiron-7368:/media/erikaris/DATA/ODU/Semester 3/intro_to_info_retrieval/aserikaris/DATA/ODU/Semester 3/intro_to_info_retrieval/aserikaris/DATA/ODU/Semester 3/intro_to_info_retrieval/aserikaris/DATA/ODU/Semester 3/intro_to_info_retrieval/aserikaris/DATA/ODU/Semester 3/intro_to_info_retrieval/aserikaris/DATA/ODU/Semester 3/intro_to_info_retrieval/aserikaris/DATA/ODU/Semester 3/intro_to_info_retrieval/aserikaris/DATA/OD
```

Figure 6: Terminal input for running the inverted index

```
2 #!/usr/bin/python
3 import unicodecsv as csv
4 import io
5 import os
6 import sys
8 import html2text
9 from tabulate import tabulate
11 # Assuming all arguments are file
12 \text{ files} = []
for arg in range(1, len(sys.argv)):
      files.append(sys.argv[arg])
14
15
file_words_index = \{\}
17
  all words = set()
19 # Read all files
  for file in files:

21
      # get text content
      h = html2text.HTML2Text()
22
23
      h.ignore links = True
      text = h.handle(u' '.join([line.strip() for line in io.open(file, "r", encoding="
24
      utf-8"). readlines()])
25
      words = [word.lower() for word in text.split() if word.isalpha()]
26
      all words |= set (words)
27
      file\_words\_index[file.split(os.pathsep)[-1]] = words
28
30 # Invert words and files
31 word files index = {}
```

```
for word in all words:
32
      files = []
33
      for file , words in file_words_index.items():
34
           if word in words:
35
               files.append(file)
36
      word_files_index[word] = sorted(set(files))
37
38
  # Convert to 2d array
39
  table = []
40
  for word in word_files_index:
41
      table.append([word, u', '.join(word_files_index[word])])
42
43
44
  print tabulate(table, headers=["word", "files"])
45
46 # write the output to csv file
47 out_file = os.path.join(os.getcwd(), '5_8-inverted_index.csv')
  with open(out_file, "wb") as f:
      writer = csv.writer(f)
49
      writer.writerow(["word", "files"])
50
      writer.writerows(table)
```
